(54) Title: TREATMENT OF HYPERTENSION

(57) Abstract

Novel methods are provided for treating hypertension in humans which comprise administering therapeutic amounts of pharmaceutically-acceptable non-halide salts of potassium. Preferred salts are potassium bicarbonate and potassium phosphate. The methods may also be used to lower the blood pressure of normotensive individuals. Dietary supplementation is a preferred and convenient method of administration.

GOVERNMENT SUPPORT

This invention was made with Government support under Grant No. M01-RR0079 awarded by the National Institutes of Health. The Government has certain rights in this invention.

15

FIELD OF THE INVENTION

20

This invention concerns novel methods for treating and diagnosing hypertension in humans and, more particularly, involves administration of pharmaceutically-acceptable non-halide potassium salts, such as potassium bicarbonate, in a variety of dietary and pharmaceutical compositions.

BACKGROUND OF THE INVENTION

25

30

35

Hypertension is an insidious disease which affects many people. Hypertension is generally defined as an abnormally increased blood pressure. It is clinically recognized as an elevation of systolic arterial blood pressure of 150 mm Hg or greater and/or an elevation of diastolic arterial blood pressure of 90 mm Hg or higher. Certain risk factors, e.g., hypercholesterolemia, diabetes, smoking, and a familial history of vascular disease, in conjunction with hypertension may predispose individuals to arteriosclerosis and consequent cardiovascular morbidity and mortality.

During the past three decades, morbidity and mortality resulting directly or indirectly from hypertension have fallen with the development of effective

pharmacological agents. Several anti-hypertensive drugs that act predominantly on the peripheral sympathetic nervous system, adrenergic receptors, autonomic ganglia, and/or on the renin-angiotensin system have been described and
5 include, for instance, propranolol, methyldopa, clonidine, and prazosin, to name but a few. Diuretic agents have also become a mainstay in anti-hypertensive therapy, and include thiazides and closely related phthalimidine derivatives, e.g., chlorthalidone. Others, such as hydralazine, act as
10 vasodilators by causing the direct relaxation of arteriolar vascular smooth muscle.

In general, however, drug therapy for hypertension is reserved for those individuals whose blood pressure cannot be maintained in an acceptable range by non-
15 pharmacological means. Of the non-pharmacological treatments for hypertension, weight reduction and salt (sodium chloride) restriction have been considered to be the most successful. Restricting dietary salt, although of somewhat limited and unpredictable effect, can in some cases
20 reduce diastolic blood pressure to an extent comparable to that achieved by treatment with some of the pharmacologic agents.

Patients whose cause of hypertension is not readily apparent are said to have "essential hypertension."
25 This group comprises approximately 95% of the patients treated for hypertension. Patients with essential hypertension whose blood pressure decreases with restriction of dietary sodium chloride and increases with its subsequent supplementation are characterized as having "salt-
30 sensitivity" or, more precisely, "sodium chloride-sensitive" hypertension. Fujita et al., Am. J. Med. (1980) 69:334 and Kurtz et al., N. Engl. J. Med. (1987) 317:1043. Certain elements of the population have been reported to be more salt-sensitive than others, and thus exhibit greater blood
35 pressure changes when subjected to different dietary intakes of NaCl (see, for example, Weinberger, et al., J. Am. Coll. Nutr. 1:139-148, 1982; Luft, et al., Am. J. Med. 72:726-736,

1982; Dustan, et al., Am. J. Med. Sci. 295:378-383, 1988; and Sullivan, et al., Am. J. Med. Sci. 295:370-377, 1988.

5 The prevalent view is that the capacity of sodium chloride to increase blood pressure depends only on its sodium component and that, hence, all commonly ingested sodium salts have this capacity (Sodium and Potassium in Foods and Drugs: NAK Conference Proceedings, White and Crocco, eds., Amer. Med. Assn., Chicago, 1980; Willis, ed., FDA Drug Bulletin (1983) 13:25). A standard pharmacological
10 textbook, Goodman and Gilman, The Pharmacological Basis of Therapeutics, 7th Ed., 1985, recommends that sodium restriction should be encouraged for hypertensive patients and used as a definitive therapy if effective.

 Some studies have suggested that the anion
15 component of a dietary sodium salt may determine the extent to which that sodium salt induces an increase in blood pressure. Kurtz et al., Science (1983) 222:1139; Whitescarver et al., Science (1984) 223:1430; and Kurtz et al., New Engl. J. Med., (1987), 317:1043. These studies
20 suggest that both the sodium and chloride ions of NaCl are required for its capacity to increase blood pressure.

 The results of clinical and epidemiological studies suggest that the amount of potassium in the diet may also be an important determinant of blood pressure in
25 patients with hypertension and, in some instances, in normotensive subjects. It has been observed that increasing potassium intake by the administration of a dietary supplement of potassium tends to lower blood pressure. (Addison, et al., Can. Med. Assoc. 18:281-285, 1928; Morgan, et al., Clin. Sci. 63:407s-409s, 1982; Holly, et al., Lancet
30 2:1384-1387, 1981; Fujita, et al., Hypertension 6:184-192, 1984; MacGregor, et al., J. Cardiovasc. Pharmacol. 6:S244-S249, 1984, Siani et al., Br. Med. J. 294:1453-1456; and Obel, J. Cardiovasc. Pharmacol. 14:294-296, 1989). The
35 anti-hypertensive effect of increasing potassium intake, however, has usually been small and variable.

In one experimental program, the blood pressure-lowering effect of dietary potassium supplementation was insignificant in patients on moderately restricted NaCl diets. Smith, et al., Br. Med. J. (1985) 290:110. Indeed, no anti-hypertensive effect of potassium was observed in studies by some investigators. See, Richards et al., Lancet (1984) 1:757 and Skrabal et al., Klin. Wochenschr. (1984) 62:124.

The possible use of a potassium salt other than potassium chloride, namely potassium citrate, to treat hypertension has also been suggested in the technical literature. Addison, Id. In that report, summarizing experiments on five subjects on "salt-poor diets", potassium citrate was said to exhibit a blood pressure lowering effect. Addison claimed that potassium citrate was more effective than potassium chloride in two of the three patients in whom he compared the hypotensive effect of the two potassium salts. In neither of these two instances, however, does the reported data justify the claim that potassium citrate was more effective than potassium chloride in reducing blood pressure. Indeed, to our knowledge, potassium citrate has not been recommended as a therapy for hypertension in any publication in the medical literature in the sixty years since the date of the Addison paper.

What is still urgently needed is an effective method for treating essential hypertension which utilizes a potassium compound that may be conveniently administered, preferably as a dietary supplement, which avoids concomitant administration of chloride, which is relatively easy to manufacture in bulk, and which may be made available at comparatively low cost. The present invention fulfills these and other related needs.

SUMMARY OF THE INVENTION

The present invention involves a novel method for ameliorating or preventing hypertension in humans afflicted with or predisposed to hypertension, which method comprises

administering a therapeutically- or prophylactically-effective amount of a composition of a pharmaceutically-acceptable potassium salt in which the anion component is not a chloride or other halide. The potassium salt may be
5 selected from the group consisting of potassium bicarbonate, potassium phosphate, or an alkalinizing potassium salt of a carboxylic acid, e.g., potassium gluconate and potassium citrate, among others. In particularly preferred
10 embodiments the salts are potassium bicarbonate and potassium phosphate.

The non-halide potassium salt may be administered to ameliorate or prevent hypertension in any of several therapeutically- or prophylactically-acceptable forms and by a variety of routes. The compositions may conveniently be
15 formulated and administered as a dietary supplement. An effective dosage of potassium bicarbonate is typically about 50-250 millimoles (mmoles) per 70 kg body weight per day.

In accordance with this invention it is particularly preferred to administer the non-halide
20 potassium salt as a dietary supplement to patients on nutritionally adequate whole-foods diets that have "normal" salt (NaCl) contents (about 75 to 300 meq. of Na per day). It has been found that administration of the potassium salt in this way is particularly effective in ameliorating
25 hypertension.

Moreover, administration of the non-halide potassium salt is believed to attenuate increases of blood pressure otherwise induced by dietary NaCl in salt-sensitive individuals. The non-halide potassium therapy thus protects
30 salt-sensitive individuals against extreme blood pressure elevations which might otherwise occur when they are on high salt diets.

Also provided as part of the invention are methods for diagnosing individuals susceptible to or suffering from
35 hypertension which is or will be amenable to treatment with a non-halide potassium salt.

DESCRIPTION OF THE FIGURES

FIG. 1 is a graph showing the results of administering 200 mmoles of potassium bicarbonate per 70 kg. body weight per day in four oral doses on each of 15 days to two male patients having essential hypertension. In the graph each patient's mean arterial pressure (MAP) is plotted against time for a pre-treatment "Control" period, a " KHCO_3 " treatment period, and a "Recovery" period. Filled bars represent the differences between the control average MAP for the 10-day steady-state control period (represented by the horizontal line) for one patient, and unfilled bars represent the data for the second patient. Bars above the zero line indicate MAP values exceeding the control period average, and bars below the line indicate MAP values lower than the control period average;

FIG. 2 is a graph similar to FIG. 1, showing the results of administering approximately 100 mmoles of potassium bicarbonate per 70 kg. body weight per day for eight days to five normotensive males. The bar for each day represents the average change in the MAP value for the group from the control period; and

FIG. 3 is another graph similar to FIGS. 1 and 2, containing separate plots of the average systolic and diastolic MAP values against time for six post-menopausal normotensive women.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In accordance with the present invention, novel methods are provided for preventing or ameliorating hypertension, which comprises administering to subjects a potassium salt in which the anion component is other than chloride or other halide in amounts sufficient to provide the desired physiological benefit while avoiding amounts sufficient to induce undesirable toxic effects.

As used herein, the terms "treatment" or "treating" relate to any treatment of hypertensive disease, and include: (1) preventing hypertension from occurring in a

subject who may be predisposed to the disease but who has not yet been diagnosed as having it; (2) inhibiting the disease, i.e., arresting its development; or (3) ameliorating or relieving the symptoms of the disease, i.e., causing regression of the hypertensive state.

One hypothesis for the results achieved by the present treatment, offered by way of explanation but not limitation, is that the increase of chloride or other halide upon the administration of potassium chloride or the like, induces physiological changes that antagonize or otherwise counter or mask the anti-hypertensive effect of potassium. Accordingly, subjects who do not exhibit a lowering of blood pressure in response to the administration of potassium chloride or bromide may show a response to a non-halide salt of potassium, and patients who have shown some anti-hypertensive response to potassium chloride or bromide may show a substantially greater response when a non-halide potassium salt is used instead.

The non-halide potassium salts which may be employed in the process of the present invention are those which exhibit the ability to decrease the systolic or diastolic blood pressure of an individual without significant undesirable side effects. A number of pharmaceutically-acceptable salts are known, several of which are set forth in Berg et al., J. Pharmaceut. Sci. (1977) 66:1, which is incorporated herein by reference. It is known that the chloride ion acts as a pressor or contributes to the pressor effect in formulations of sodium chloride (Kurtz et al., N. Engl. J. Med. (1987) 317:1043, which is incorporated herein by reference). Given the disclosure herein, it will be well within the ability of one skilled in the art to select and screen pharmaceutically-acceptable potassium salts for the ability to lower blood pressure using well known methods and techniques. Desirably, a potassium salt will be selected which is therapeutically effective in amounts readily achievable in humans while being relatively well tolerated.

Different salts may be chosen depending on particular routes of administration and preferred modes of formulation. Additionally, it may be preferred to select potassium salts which, upon administration, produce a slight systemic alkalization, which alkalization itself may contribute to a vasodilatory effect that augments a specific vasodilatory effect conferred by the potassium ion. A bicarbonate component or metabolite generated promptly after administration or ingestion of the salt may thus not only alkalize the blood, but it may affect the distribution of fluids between the vascular and extravascular compartments. Blood pH and bicarbonate levels may be determined using well accepted methods long known to those skilled in the arts.

The potassium salts which may be thus administered are preferably selected from the group consisting of potassium bicarbonate (KHCO_3), potassium phosphate (K_2HPO_4 or a mixture of K_2HPO_4 and KH_2PO_4), potassium gluconate ($\text{C}_6\text{H}_{11}\text{KO}_7$) and potassium citrate ($\text{C}_6\text{H}_5\text{K}_3\text{O}_7$). The use of potassium bicarbonate and potassium phosphate is particularly preferred in this invention.

The preparation, isolation and purification of these salts are well known to those skilled in the art, as they are commonly employed in a therapeutic setting for a variety of uses other than described herein. Specific preparation procedures for each salt are described in general terms in Remington's Pharmaceutical Sciences, Mack Publishing Company, Easton, Pennsylvania, 16th Ed., 1982, which is incorporated herein by reference.

Administration of a non-halide potassium salt as an active compound may be in a pharmaceutical composition described hereinafter and can be via any of the accepted modes of administration for agents which are known to affect hypertension. These methods include oral, parenteral, and other modes of systemic administration. Different non-halide potassium salts may be admixed and simultaneously administered, or benefit may be gained in some instances by their separate, sequential administration.

Depending on the intended mode, the compositions may be in the form of solid, semi-solid or liquid dosage forms, such as, for example, tablets, capsules, pills, powders, granules, crystals, liquids, suspensions, or the like, preferably in unit-dosage forms suitable for administration of relatively precise dosages. The compositions may include a conventional pharmaceutical carrier or excipient and, in addition, may include other medical agents, pharmaceutical agents, carriers, etc.

The amount of the non-halide potassium salt administered in accordance with the present invention will, of course, be dependent on the subject being treated, the severity of the affliction, the manner of administration, and the judgment of the prescribing physician. However, an effective dose of potassium bicarbonate, for instance, will be in the range of 50-300 mmoles/70 kg/day, preferably 50-250 mmoles/70 kg/day. Dosages may be adjusted by monitoring the effects of the amount administered and adjusting subsequent amounts as appropriate.

Many of the potassium salts of the invention may be administered in relatively large amounts without serious side effects, although indiscriminate use of potassium salts may produce toxic manifestations of hyperkalemia and gastrointestinal irritation. In cases where the compound is administered to prevent the emergence of hypertension in normotensive subjects susceptible to hypertension, or those suffering from only mild or borderline hypertension, the dose may be adjusted accordingly to lower maintenance levels.

For solid compositions, the non-halide potassium salts such as potassium bicarbonate may be provided separately or may be compounded with conventional nontoxic solid carriers such as, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, talcum, cellulose, glucose, sucrose, magnesium carbonated, and the like. Liquid pharmaceutically-administrable compositions can be prepared, for example, by dissolving the salt, such

as potassium bicarbonate, and optional pharmaceutical adjuvants in a carrier, such as, for example, water, aqueous dextrose, glycerol, and the like, to thereby form a solution or suspension. If desired, the pharmaceutical composition to be administered may also contain minor amounts of nontoxic auxiliary substances such as pH buffering agents and the like, for example, sorbitan monolaurate, triethanolamine, sodium acetate, triethanolamine oleate, etc. Actual methods of preparing such dosage forms are known, or will be apparent, to those skilled in this art; see, for example, Remington's Pharmaceutical Sciences, Mack Publishing Company, Easton, Pennsylvania, 16th Ed., 1982, which is incorporated herein by reference. The composition or formulation to be administered will, in any event, contain a quantity of the non-halide potassium salt in an amount effective to lower the systolic and/or diastolic blood pressure and alleviate or ameliorate the symptoms thereof or prevent their emergence in the subject being treated.

For oral administration, a pharmaceutically-acceptable nontoxic composition is formed by the incorporation of any of the normally employed excipients such as, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, talcum, cellulose, glucose, sucrose, magnesium carbonate, and the like. Such compositions take the form of solutions, suspensions, tablets, pills, capsules, powders, granules, crystals, sustained-release formulations, and the like. Such compositions may contain about 10-100% active ingredient, preferably about 25-90%. As a dietary supplement potassium bicarbonate, for example, may be supplied as granules or powder and applied directly to foodstuffs or dissolved in drinking water as a convenient means of administration.

The compositions useful in the methods of the invention may be supplied in containers having printed instructions which direct the user to employ the compositions in the methods and for the purposes described

herein. Accordingly, said containers having such instructions are considered part of the present invention. The instructions for use may be printed on the container or on a separate sheet which is included with the container.

5 Among other things, the instructions, may for example, direct the user to employ the composition in addition to a normal dietary intake of salt, and may also state that the purpose of such method is to inhibit or otherwise prevent symptoms of or associated with hypertension. The
10 instructions may be directed to normotensive individuals who may be predisposed to hypertension and/or to those already diagnosed as having essential hypertension.

The methods of the invention may also find use in diagnosing individuals suffering from or predisposed to
15 hypertension. More particularly, typically a baseline blood pressure for an individual undergoing said diagnosis is first determined. Then a non-halide potassium salt useful in the present invention is administered according to the methods herein described. Usually the composition will be
20 administered in an amount and for a time sufficient to produce a measurable lowering of blood pressure in individuals with hypertension or predisposed to developing hypertension and who may ultimately may be treatable with the therapeutic methods of the invention. If a person is
25 thus identified as having a drop in blood pressure from the baseline, a physician may then elect to initiate an appropriate therapy or further monitor the patient.

The following examples illustrate some
30 particularly preferred, non-limiting embodiments of the invention.

Example 1

Effect of Potassium Bicarbonate in Hypertensive Patients

35 Studies were performed in two men (ages 55 and 57) with essential hypertension to demonstrate that a non-halide

salt of potassium, potassium bicarbonate, lowered blood pressure. In both patients, hypertension was confirmed on at least three occasions in an out-patient setting after the patient had been sitting quietly for all least 10 minutes.

5 In patient 1, the blood pressure ranged from 141/85 to 157/94 mm Hg; in patient 2, it ranged from 144/93 to 156/100 mm Hg. Neither of the patients had clinical signs or symptoms of pheochromocytoma or renal-artery stenosis, and neither had clinical or laboratory evidence of impaired
10 cardiac, renal, or hepatic function. Urinalysis and the serum concentrations of creatinine, sodium, and potassium were within normal limits in both.

All medications were stopped for each individual for at least four weeks before the beginning of the study.
15 Both patients remained hospitalized throughout the study, where physical activity consisted only of daily walks. Throughout the study, each patient ate a constant amount of a nutritionally adequate whole-foods diet intrinsically low in sodium chloride (approximately 10 mmoles NaCl/70 kg body weight/day). A sodium chloride supplement was added in an
20 amount sufficient to increase total sodium intake to 140 meq/day/70 kg. The diet also provided, per 70 kg/day, approximately 55 mmoles of potassium, 375 mg of calcium and 820 mg of phosphorus.

25 In each patient, the total number of calories provided was determined from the estimated amount of energy required to keep body weight constant. The diet contained, as a percentage of total calories, 35% fat, 56% carbohydrate, and 9% protein. The specific ingredients of
30 each meal were constant throughout the study. Fluid intake was fixed at 3150 ml/ 70 kg/day.

A 10-day steady-state control period preceded the experimental period. Throughout the experimental period, both patients took an aqueous solution containing potassium
35 bicarbonate, 1.0 mmoles/ml of solution; each patient ingested 200 mmoles of potassium bicarbonate/70 kg/day in

three divided doses, with meals, on each day of the study, for a total of 15 days.

Blood pressure was measured in the nondominant arm at 8 A.M., Noon, 4 P.M., 8 P.M., and 10 P.M. of each day, with an automated oscillometric device (Dinamap, 1846P). In this manner, observer bias was avoided. At each measurement session, after the patient had been supine for 10 minutes, five measurements of systolic and diastolic pressure and heart rate were obtained and the average of the last four measurements were calculated. The measurements were repeated with the patient in the upright position at each session. The measurements were averaged to yield values for daily systolic and diastolic blood pressures. Mean arterial pressure was calculated as $(\text{systolic pressure} - \text{diastolic pressure})/3 + \text{diastolic pressure}$.

The results of the study are shown in FIG. 1. The figure plots the difference of each day's mean arterial pressure (MAP) from the average MAP for the entire control period, represented by the horizontal zero line. Bars extending above the zero line indicate MAP values exceeding the control period average, and vice versa. Filled bars represent one patient, unfilled bars, the other.

Both patients had significant reductions in systolic, diastolic, and mean arterial pressures occurring promptly on initiating potassium bicarbonate treatment (day 1) and persisting for the 15-day treatment period. Heart rate increased during potassium bicarbonate treatment. Subject No. 1 manifested a significant rebound overshoot of blood pressure when the potassium bicarbonate was discontinued, and Subject No. 2 manifested a similar tendency early in the recovery period. No adverse effects of potassium bicarbonate administration were observed in either subject.

Example 2Effect of Potassium Bicarbonate in
Normotensive Individuals

5 In a study performed similarly to that described
in Example 1, the effect of potassium bicarbonate on the
blood pressure in normotensive individuals was determined.
The group consisted of five men, ages 40-53. The
equilibration or control period consisted of 7 days, the
treatment with potassium bicarbonate 8 days, and the
10 recovery period an additional 8 days. Each subject ingested
a daily potassium bicarbonate supplement of 100 meq/70
kg/day, making the total potassium intake approximately 150
meq/70 kg/day. The subjects were fed a diet having an
intrinsic low-sodium chloride content (less than 10 meq
15 sodium and chloride/day/70 kg body weight) and a normal
potassium content (52 meq/day/70 kg body weight). A sodium
chloride supplement was added sufficient to increase total
sodium intake to 140 meq/70 kg/day.

The results of the study on the normotensive
20 subjects is shown in FIG. 2. Each day's bar represents the
groups' average change in mean arterial pressure from the
control for that day. As with the hypertensive individuals,
the administration of potassium bicarbonate resulted in
significant reductions in mean arterial pressures, occurring
25 promptly on initiating potassium bicarbonate treatment and
persisting for the treatment period. The reduction in mean
arterial pressures was also manifested during a portion of
the recovery period. Thus potassium bicarbonate was shown
to be effective in lowering blood pressure in normotensive
30 individuals and may readily find prophylactic use in
preventing the onset of hypertension in individuals
identified as predisposed to the condition.

Example 3Effect of Potassium Bicarbonate
in Normotensive Post-Menopausal Women

5 In six post-menopausal women (ages 52-65) who were not hypertensive, potassium bicarbonate was administered in an amount of 120 mmoles per kg body weight per day for 18 days. A significant and sustained reduction in both systolic and diastolic blood pressures resulted (see FIG. 3).

10 Blood pressures were measured without observer bias by use of an automated blood pressure reader-recorder, which in addition, gave improved accuracy by performing quadruplicate readings at each measurement session.

15 The studies were performed while the patients resided in the University of California General Clinical Research Center (Moffitt Hospital). Throughout the period of residence, the patients ate a constant diet of known composition, comprising (per 60 kg body weight) 546 mg calcium, 948 mg phosphorus, 60 meq sodium, and 56 meq potassium. A supplement of sodium chloride of 60 mmoles/day was provided, making total sodium intake 120 meq per 60 kg body weight per day. Fluid intake was fixed.

20 The subjects were allowed 10 days for their bodies to equilibrate and adapt to the fixed diet. There then followed, immediately and in succession, a 12-day control period (CONTROL) prior to initiation of KHCO_3 administration, an 18-day period of KHCO_3 administration, and a 12-day recovery period after discontinuation of KHCO_3 .

25 FIG. 3 shows the changes in systolic (upper panel) and diastolic (lower panel) blood pressures. For each subject, the average value of systolic blood pressure for the entire CONTROL period was subtracted from each day's systolic blood pressure, thereby generating a "difference from CONTROL" value for every day of the study, including the individual control days. For each day of the study, the average of the daily "differences from CONTROL" were calculated for the entire group of six subjects, and those

were plotted in the figure as vertical bars. Vertical bars extending below the zero line represent decreases in systolic blood pressure relative to the average control value; vertical bars extending above the zero line represent increases in systolic blood pressure relative to the control value. A similar procedure was used for diastolic blood pressure.

The KHCO_3 administration resulted in a prompt and sustained reduction in both systolic and diastolic blood pressures. After discontinuation of KHCO_3 , the pressures gradually returned to control.

The results obtained in this experiment demonstrate that KHCO_3 lowers blood pressure in normotensive post-menopausal women.

From the foregoing, it will be appreciated that the present invention provides methods which effectively ameliorate/prevent hypertension in humans. Because many of the non-halide potassium salts such as potassium bicarbonate are naturally-occurring and readily available, their use as a dietary supplement or otherwise present the possibility of a purely nutritional approach to hypertension, thereby avoiding the disadvantages of conventional pharmacological intervention.

Although the present invention has been described in some detail by way of illustration and example for purposes of clarity and understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.

WHAT IS CLAIMED IS:

1. A method for treating hypertension in an individual, which comprises administering a therapeutic amount of a composition of a pharmacologically-acceptable potassium salt of a non-halide anion.
2. The method according to claim 1, for treating hypertension in an individual, which comprises treating a hypertensive subject or a normotensive subject susceptible to hypertension with said potassium salt.
3. The method according to claim 1, wherein said potassium salt is selected from the group consisting of potassium bicarbonate, potassium phosphate, potassium gluconate, and potassium citrate.
4. The method according to claim 3, wherein said salt is potassium bicarbonate.
5. The method of claim 3, wherein the potassium salt is administered as a dietary supplement.
6. A method for treating hypertension in an individual which comprises administering a therapeutically-effective amount of a composition of potassium bicarbonate.
7. The method of claim 6, for treating hypertension in an individual, which comprises treating a hypertensive subject, or a normotensive subject susceptible to hypertension, with said potassium bicarbonate composition.
8. The method of claim 6, wherein the potassium bicarbonate is administered orally.

9. The method of claim 8, wherein the potassium bicarbonate is administered as a dietary supplement.

10. The method of claim 6, wherein the potassium bicarbonate is administered in an amount of from about 50-200 mmoles/70 kg body weight/24 hours.

11. The method of claim 6, wherein the composition includes a pharmaceutically-acceptable carrier.

12. A method of preventing the emergence of hypertension in normotensive subjects susceptible to hypertension, which comprises administering to said subjects a non-halide potassium salt selected from the group consisting of potassium bicarbonate and potassium phosphate in an amount sufficient to lower the arterial blood pressure of said subjects.

13. A method of diagnosing an individual susceptible to or suffering from hypertension which is treatable with a non-halide potassium salt, which method comprises measuring said individual's blood pressure to obtain a first value, administering a non-halide potassium salt to said individual, measuring the blood pressure to obtain a second value, and comparing said first and second values and therefrom diagnosing said individual.

14. The method of claim 13 wherein said non-halide potassium salt is administered in an amount and for a time sufficient to cause a measurable lowering of blood pressure in individuals responsive to non-halide potassium salt therapy or prophylaxis.

15. The method of claim 14 wherein said non-halide potassium salt administered to said individual is potassium bicarbonate.

16. The method of claim 14 wherein said non-halide potassium salt administered to said individual is potassium phosphate.

5 17. A container having a non-halide potassium salt and printed instructions for using said salt for treating hypertension in a hypertensive or normotensive subject.

10 18. The container of claim 17, wherein said instructions are printed on said container.

 19. The container of claim 17, wherein said salt is potassium bicarbonate.

15 20. The container of claim 17, wherein said salt is potassium phosphate.
